ABSTRACT

Introduction: Schizophrenia is a disabling, chronic mental disorder that gives rise to numerous challenges in its management and consequences. It exerts a significant cost of the patient in terms of personal suffering, on the caregivers a result of the shift of burden of care from hospital to families, and on society at large in term of significant direct and indirect cost that include frequent hospitalizations and need for long term psychological and economic support as well as life time last productivity. Aim and Objectives: This systematic review analyzes caregivers burden, stress and coping mechanism among family caregivers of Schizophrenic patients. Methods: The systematic review was conducted to determine caregivers burden, stress and coping mechanism in family caregivers of Schizophrenic patients. No date limitations were imposed for search. The National and International Journal, Pub Med, Google search databases were searched. The key words family caregivers burden, stress, coping were used as search terms. The study inclusion criteria were: study conducted with family caregivers of Schizophrenic patient. It exclusion criteria were : studies conducted with families caregivers of other than Schizophrenic. Results: Burden, The collective studies reveal that there was 31.6% mild burden, the prevalence of moderate burden is 48.1% and studies reveal that severe burden is prevalent in 15.6%, Stress, The overall result of studies showed that 52.5% is mild stress. Moderate stress prevails in 86% and severe stress is present in 14%, Co-relation, Collective studies reveal that higher the level of stress lower the coping strategies. \( r = -0.341 \), Mean Score: Studies reveal that the mean score of ZBI scale is 44.88.

Keywords: Caregivers burden, stress, coping mechanism, systematic review

INTRODUCTION

Caregiving for Schizophrenia is often provided by family members or other close persons and plays an important role in ensuring that people with this mental illness are able to live life to the fullest. However, it is natural for caregivers of persons with Schizophrenia to experience feelings of frustration, burden, stress and difficult in coping when placed in this role. As a caregiver, you have to serve as both a support system for your family members and a liaison for their medical store. In other words, learning curve and its simply not easy. Not only do you need to quickly learn about and understand the illness and the board range of behaviours that it can involve, but you also need to determine how best to provide care without overstepping or creating undue stress. The more that a person with Schizophrenia can do for themselves, the better of
they will be in terms of their own self-esteem and having hope for the future. For this reason, as a caregiver, you should be encouraging the use of coping skills and self-help strategies for areas of life that are affected by the illness. In this way, you are helping to empower the person with Schizophrenia by helping them to do all that they are capable of doing.

**OBJECTIVES**

This systematic review analyzes caregiver’s burden, stress and coping among family caregivers of Schizophrenic patients.

**METHODS**

**Study Identification**— No date limitations were imposed for search. The National and International Journal, Pub Med, Google search databases were searched.

**Inclusion Criteria:** Study conducted with family caregivers of Schizophrenic patient.

**Exclusion Criteria:** Studies conducted with families caregivers of other than mental illness.

**STUDY SELECTION:**

The researchers search identified a total of 44 studies from the International Journals (6), the national Journals (9), the higher education thesis (5), and Pub Med (24). Some studies were excluded from this study, because 6 were same and 26 were irrelevant. The remaining 14 studies were reassessed in terms of the study's inclusion and exclusion criteria. Finally, 2 studies were included and were examined.

FINDINGS

The General characteristics of the studies: There was no date limitations impose for search. Of the studies included, 11 had descriptive studies, 1 non-experimental descriptive survey design, 1 non-experimental cross-sectional descriptive design and one pretest-post test quasi experimental research design. Of the studies 11 involved caregivers for patients with Schizophrenia; 1 involved caregivers for psychiatric patients; 1 involved caregivers for hospitalized patients; 1 involved caregivers for mentally ill patients. The study found that, among descriptive studies included, the study by Tanriverdi D (2012) had the smallest study sample with 31 caregivers, and the study by Kizilirmak B. (2016) had the largest study with 243 caregivers.

THE MEASUREMENTS TOOL USED AND THEIR RESULTS:

A variety of measurement tools were used to assess the caregivers of burden, stress and coping among family caregivers of Schizophrenic patients:- The modified stress scale (1), Modified coping Scale, (1) Structured Interview Schedule (1), Coping Strategies Scale (1), CoPEScale (1), ZBI-22 (6), Burden Assessment Scale (BAS) (3), Perceived Family Burden Scale (1).

Zarit Burden Interview:

Of the studies taken under analysis using the ZBI, 2nd, 3rd, 4th and 5th studies concluded that the burden was above 50%. The total number of studies taken under the analysis using ZBI are 6. A study by EsraYaziki concluded that there was no significant co-relation between the caregivers knowledge about Schizophrenia and Caregivers burden (P < 0.05 >). A study conducted by Kinari, 2011 concluded that the mean score of caregivers burden was 42.05.

Burden Assessment Schedule:

A study by Shiba K., 2018 found that the score of burden of care showed that the burden of Care was more among female spouses. The study by Sunanda G.T., Ramesh C. showed that the psycho education to caregivers of patient with Schizophrenia may have significant impact on reducing their burden level.

Modified Stress Scale:

Silas Treveli M., Sheela Upendri 2018, conducted a study among family members of patients with Schizophrenia found that higher the level of stress, lower the coping strategies. The study reveals that provision of psycho education may reduce the stress among family members of patients with Schizophrenia.

Modified Coping Scale:

Study conducted by Kamala Darlani et.al., (2015) revealed that the most of caregivers of psychiatric illness were found to be stressed and used active coping measures to manage their stress.

Structural Interview Schedule:

A study conducted by Urmila D. Bhardwaj, Jamal Fatima Hashmi, 2018 used this scale and showed that there was a negative (inverse) co-relation between coping and stress.

Kingston Caregivers Stress Scale:

A study by Kamala Darlami et.al.; (2015) used this scale and concluded that majority of the respondents were at moderate (86%).

Coping Strategies Scale:

A study done by Urmila D. Bhardwaj, Jamal Fatima Hashmi, 2018 concluded that family members of Schizophrenic patients were majority stress (65%).
COPE Scale:
A study by Kamala Darlami et al. (2015) used this scale and showed that the most of the caregivers of Psychiatric illness were found that they are stressed (86).

Perceived Family Burden Scale:
A study conducted by Arsalant as H. 2012 used this scale and concluded that subjective burden mean score of caregivers was 28.9, their objective burden mean score was 8.7.

Result: Burden, The collective studies reveal that there was 31.6% mild burden, the prevalence of moderate burden is 48.1% and studies reveal that severe burden is prevalent in 15.6%. Stress, The overall result of studies showed that 52.5% is mild stress. Moderate stress prevails in 86% and severe stress is present in 14%, Co-relation, Collective studies reveal that higher the level of stress lower the coping strategies. r = -0.341, Mean Score: Studies reveal that the mean score of ZBI scale is 44.88.

CONCLUSION:
The studies were analyzed to find the stress, burden and coping among family caregivers of Schizophrenic patients.

Stress:
The stress showed that medium level stress was present, mean score was (60%) with overall coping ability of 40%. Purposive sampling and descriptive survey approach were mainly used with descriptive research designs. Modified stress scale30 and modified coping scale w as used. The result of these studies showed that close monitoring of caregivers, mental health and provision of psycho education family intervention may reduce the stress among caregivers.

Burden:
The study findings revealed that majority of subject (47%) experienced moderate burden. Collectively it was found that there was significant association between burden and the selected variables. Studies showed that the score of burden was more among female spouses. BAS and ZBI-22 tools were used in studies.

Purposive sampling technique and cross sectional survey designs were used.
Stress and Burden was somehow decreased after providing psycho education to caregivers.
